Simplified Cost Function and Gradient Descent

Note: [6:53 - the gradient descent equation should have a 1/m factor]

We can compress our cost function's two conditional cases into one case:

$$\mathrm{Cost}(h_{\theta}(x),y) = {} - y \log(h_{\theta}(x)) - (1-y) \log(1-h_{\theta}(x))$$

Notice that when y is equal to 1, then the second term $(1-y)\log(1-h_{\theta}(x))$ will be zero and will not affect the result. If y is equal to 0, then the first term $-y \log(h_{\theta}(x))$ will be zero and will not affect the result.

We can fully write out our entire cost function as follows:

$$J(\theta) = \, -\, \tfrac{1}{m} \sum_{i\, =\, 1}^m \left[y^{(i)} \log (h_\theta(x^{(i)})) + (1-y^{(i)}) \log (1-h_\theta(x^{(i)})) \right]$$

A vectorized implementation is:

$$\begin{split} h &= g(X\theta) \\ J(\theta) &= \frac{1}{m} \cdot \left(-y^T \log(h) - \left(1 - y\right)^T \! \log(1 - h) \right) \end{split}$$

Gradient Descent

Remember that the general form of gradient descent is:

$$\begin{aligned} &Repeat~\{\\ &\theta_j := \theta_j - \alpha \, \frac{\partial}{\partial \, \theta_j} \, J(\theta) \\ &\} \end{aligned}$$

We can work out the derivative part using calculus to get:

$$Repeat~\{$$

$$\theta_j := \theta_j - \frac{\alpha}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

$$\}$$

Notice that this algorithm is identical to the one we used in linear regression. We still have to simultaneously update all values in theta.

A vectorized implementation is:

$$\theta := \theta - \tfrac{\alpha}{m} \boldsymbol{X}^T (g(\boldsymbol{X}\theta) - \overset{\longrightarrow}{\boldsymbol{y}})$$
